## Definitions of Managed Objects for Scheduling Management Operations

### Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

### Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes a set of managed objects that are used to schedule management operations periodically or at specified dates and times.

This document obsoletes RFC 2591.

## 1. Introduction

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes a set of managed objects that are used to schedule management operations periodically or at specified dates and times.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

## 2. The SNMP Management Framework

The SNMP Management Framework presently consists of five major components:

- o An overall architecture, described in RFC 2571 [RFC2571].
- o Mechanisms for describing and naming objects and events for the purpose of management. The first version of this Structure of Management Information (SMI) is called SMIV1 and described in STD 16, RFC 1155 [RFC1155], STD 16, RFC 1212 [RFC1212] and RFC 1215 [RFC1215]. The second version, called SMIV2, is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].
- o Message protocols for transferring management information. The first version of the SNMP message protocol is called SNMPv1 and described in STD 15, RFC 1157 [RFC1157]. A second version of the SNMP message protocol, which is not an Internet standards track protocol, is called SNMPv2c and described in RFC 1901 [RFC1901] and RFC 1906 [RFC1906]. The third version of the message protocol is called SNMPv3 and described in RFC 1906 [RFC1906], RFC 2572 [RFC2572] and RFC 2574 [RFC2574].

- o Protocol operations for accessing management information. The first set of protocol operations and associated PDU formats is described in STD 15, RFC 1157 [RFC1157]. A second set of protocol operations and associated PDU formats is described in RFC 1905 [RFC1905].
- o A set of fundamental applications described in RFC 2573 [RFC2573] and the view-based access control mechanism described in RFC 2575 [RFC2575].

A more detailed introduction to the current SNMP Management Framework can be found in RFC 2570 [RFC2570].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the mechanisms defined in the SMI.

This memo specifies a MIB module that is compliant to the SMIV2. A MIB conforming to the SMIV1 can be produced through the appropriate translations. The resulting translated MIB must be semantically equivalent, except where objects or events are omitted because no translation is possible (use of Counter64). Some machine readable information in SMIV2 will be converted into textual descriptions in SMIV1 during the translation process. However, this loss of machine readable information is not considered to change the semantics of the MIB.

### 3. Overview

The MIB defined in this memo provides the scheduling of actions periodically or at specified dates and times. The actions can be used to realize on-duty / off-duty schedules or to trigger management functions in a distributed management application.

Schedules can be enabled or disabled by modifying a control object. This allows for pre-configured schedules which are activated or deactivated by some other management functions.

The term 'scheduler' is used throughout this memo to refer to the entity which implements the scheduling MIB and which invokes the actions at the specified points in time.

### 3.1. Periodic Schedules

Periodic schedules are based on fixed time periods between the initiation of scheduled actions. Periodic schedules are defined by specifying the number of seconds between two initiations. The time needed to complete the action is usually not known by the scheduler and does therefore not influence the next scheduling point.

Implementations must guarantee that action invocations will not occur before their next scheduled time. However, implementations may be forced to delay invocations in the face of local constraints (e.g., a heavy load on higher-priority tasks). An accumulation of such delays would result in a drift of the scheduling interval with respect to time, and should be avoided.

Scheduled actions collecting statistical data should retrieve time stamps from the data source and not rely on the accuracy of the periodic scheduler in order to obtain accurate statistics.

### 3.2. Calendar Schedules

Calendar schedules trigger scheduled actions at specified days of the week and days of the month. Calendar schedules are therefore aware of the notion of months, days, weekdays, hours and minutes.

It is possible to specify multiple values for each calendar item. This provides a mechanism for defining complex schedules. For example, a schedule could be defined which triggers an action every 15 minutes on a given weekday.

Months, days and weekdays are specified using the objects schedMonth, schedDay and schedWeekDay of type BITS. Setting multiple bits to one in these objects causes an OR operation. For example, setting the bits monday(1) and friday(5) in schedWeekDay restricts the schedule to Mondays and Fridays.

The bit fields for schedMonth, schedDay and schedWeekDay are combined using an AND operation. For example, setting the bits june(5) and july(6) in schedMonth and combining it with the bits monday(1) and friday(5) set in schedWeekDay will result in a schedule which is restricted to every Monday and Friday in the months June and July. Wildcarding of calendar items is achieved by setting all bits to one.

It is possible to define calendar schedules that will never trigger an action. For example, one can define a calendar schedule which should trigger an action on February 31st. Schedules like this will simply be ignored by the scheduler.

Finally, calendar schedules are always expressed in local time. A scalar, `schedLocalTime`, is provided so that a manager can retrieve the notion of local time and the offset to GMT time.

### 3.3. One-shot Schedules

One-shot Schedules are similar to calendar schedules. The difference between a calendar schedule and a one-shot schedule is that a one-shot schedule will automatically disable itself once an action has been invoked.

### 3.4. Time Transitions

A time transition occurs when the Schedule MIB's notion of time (as reported by `schedLocalTime`) is changed so that time continuity is lost. Time transitions may be caused by daylight savings times or administrative changes of the system's notion of time.

There are two possible situations when a time transition occurs.

First, time may be set backwards, in which case particular times will appear to occur twice. These are called 'ambiguous times'. Second, time may be set forwards, in which case particular times will not occur. These are called 'nonexistent times'.

When an action is configured in the Schedule MIB to occur at an ambiguous time, the action will be invoked at all occurrences of the ambiguous time. For example, if an action is scheduled to occur at 2:10 am, and a time transition occurs at 3:00 am which sets the clock back to 2:00 am, the action will be invoked twice.

When an action is configured in the Schedule MIB to occur at a nonexistent time, the action will not be invoked at all. For example, if an action is scheduled to occur at 2:10 am, and a time transition occurs at 2:00 am which sets the clock to 3:00 am, the action will not be invoked.

### 3.5. Actions

Scheduled actions are modeled by SNMP set operations on local MIB variables. Scheduled actions described in this MIB are further restricted to objects of type INTEGER. This restriction does not limit the usefulness of the MIB. Simple schedules such as on-duty / off-duty schedules for resources that have a status MIB object (e.g. `ifAdminStatus`) are possible.

More complex actions can be realized by triggering a management script which is responsible for performing complex state transitions. A management script can also be used to perform SNMP set operations on remote SNMP engines.

## DESCRIPTION

"This MIB module defines a MIB which provides mechanisms to schedule SNMP set operations periodically or at specific points in time."

REVISION "200201070000Z"

## DESCRIPTION

"Revised version, published as RFC 3231."

This revision introduces a new object type called schedTriggers. Created new conformance and compliance statements that take care of the new schedTriggers object.

Several clarifications have been added to remove ambiguities that were discovered and reported by implementors."

REVISION "199811171800Z"

## DESCRIPTION

"Initial version, published as RFC 2591."

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"The set of days in a month on which a scheduled action should take place. There are two sets of bits one can use to define the day within a month:

Enumerations starting with the letter 'd' indicate a day in a month relative to the first day of a month. The first day of the month can therefore be specified by setting the bit d1(0) and d31(30) means the last day of a month with 31 days.

Enumerations starting with the letter 'r' indicate a day in a month in reverse order, relative to the last day of a month. The last day in the month can therefore be specified by setting the bit r1(31) and r31(61) means the first day of a month with 31 days.

Setting multiple bits will include several days in the set of possible days for this schedule. Setting all bits will cause the scheduler to ignore the day within a month.

Setting all bits starting with the letter 'd' or the letter 'r' will also cause the scheduler to ignore the day within a month.

Note that implementations which maintain a list of pending activations must re-calculate them when this object is changed."

DESCRIPTION

```

"The type of this schedule. The value periodic(1) indicates that this entry specifies a periodic schedule. A periodic schedule is defined by the value of schedInterval. The values of schedWeekDay, schedMonth, schedDay, schedHour and schedMinute are ignored.

The value calendar(2) indicates that this entry describes a calendar schedule. A calendar schedule is defined by the values of schedWeekDay, schedMonth, schedDay, schedHour and schedMinute. The value of schedInterval is ignored. A calendar schedule will trigger on all local times that satisfy the bits set in schedWeekDay, schedMonth, schedDay, schedHour and schedMinute.

The value oneshot(3) indicates that this entry describes a one-shot schedule. A one-shot schedule is similar to a calendar schedule with the additional feature that it disables itself by changing in the 'finished' schedOperStatus once the schedule triggers an action.

Note that implementations which maintain a list of pending activations must re-calculate them when this object is changed."

## 5. Usage Examples

This section presents some examples how the scheduling MIB can be used to schedule scripts with the Script MIB [RFC3165] or to realize on-duty/off-duty schedules by modifying status objects of other MIB modules.

### 5.1. Starting a script to ping devices every 20 minutes

It is assumed that the schedule entry is owned by schedOwner = "joe" and its name is schedName = "ping". The instance identifier for the scheduling entry is therefore 3.106.111.101.4.112.105.110.103.

It is further assumed that the smLaunchTable entry is owned by smLaunchOwner = "joe" and its name is smLaunchName = "ping-devs". The complete object identifier for the smLaunchStart object is therefore

smLaunchStart.3.106.111.101.9.112.105.110.103.45.100.101.118.115.

The script lives in the context identified by the string "engine1".

The configuration of the scheduler entry which launches the script every 20 minutes would look as follows:

```

schedInterval.3.106.111.101.4.112.105.110.103 = 1200

schedValue.3.106.111.101.4.112.105.110.103 = 0
schedContextName.3.106.111.101.4.112.105.110.103 = "engine1"
schedVariable.3.106.111.101.4.112.105.110.103 =
    smLaunchStart.3.106.111.101.9.112.105.110.103.45.100.101.118.115

schedType.3.106.111.101.4.112.105.110.103 = periodic(1)
schedAdminStatus.3.106.111.101.4.112.105.110.103 = enabled(1)
schedStorageType.3.106.111.101.4.112.105.110.103 = nonVolatile(3)
schedRowStatus.3.106.111.101.4.112.105.110.103 = active(1)

```

All the remaining columns in the schedTable represent status information and are not shown here.

## 5.2. Starting a script at the next Friday the 13th

It is assumed that the schedule entry is owned by schedOwner = "joe" and its name is schedName = "13th". The instance identifier for the scheduling entry is therefore 3.106.111.101.4.49.51.116.104.

It is further assumed that the smLaunchTable entry is owned by smLaunchOwner = "joe" and its name is smLaunchName = "ghost". The complete object identifier for the smLaunchStart object is therefore smLaunchStart.3.106.111.101.5.103.104.111.115.116. The script lives in the context identified by the string "engine1".

The configuration of the scheduler entry which launches the script on the next Friday 13th at midnight would look as follows:

```

schedWeekDay.3.106.111.101.4.49.51.116.104 = { friday }
schedMonth.3.106.111.101.4.49.51.116.104 = {
    january, february, march, april, may, june,
    july, august, september, october, november, december
}
schedDay.3.106.111.101.4.49.51.116.104 = { d13 }
schedHour.3.106.111.101.4.49.51.116.104 = { h0 }
schedMinute.3.106.111.101.4.49.51.116.104 = { m0 }

schedValue.3.106.111.101.4.49.51.116.104 = 0
schedContextName.3.106.111.101.4.49.51.116.104 = "engine1"
schedVariable.3.106.111.101.4.49.51.116.104 =
    smLaunchStart.3.106.111.101.5.103.104.111.115.116

```

```

schedType.3.106.111.101.4.49.51.116.104 = oneshot(3)
schedAdminStatus.3.106.111.101.4.49.51.116.104 = enabled(2)
schedStorageType.3.106.111.101.4.49.51.116.104 = nonVolatile(3)
schedRowStatus.3.106.111.101.4.49.51.116.104 = active(1)

```

All the remaining columns in the schedTable represent status information and are not shown here.

### 5.3. Turning an interface off during weekends

This example assumes that a network interface should be taken down during weekends. The interface table (ifTable) of the IF-MIB [RFC2863] is assumed to exist in the context identified by an empty string and the index of the interface is ifIndex = 6.

The scheduling entry which brings the interface down on every Friday evening at 20:30 (8:30 pm) is owned by schedOwner = "bob" and its name is schedName = "if-off". The instance identifier for the scheduling entry is therefore 3.98.111.98.6.105.102.45.111.102.102.

```

schedWeekDay.3.98.111.98.6.105.102.45.111.102.102 = { friday }
schedMonth.3.98.111.98.6.105.102.45.111.102.102 = {
    january, february, march, april, may, june,
    july, august, september, october, november, december
}
schedDay.3.98.111.98.6.105.102.45.111.102.102 = {
    d1, d2, d3, d4, d5, d6, d7, d8, d9, d10,
    d11, d12, d13, d14, d15, d16, d17, d18, d19, d20,
    d21, d22, d23, d24, d25, d26, d27, d28, d29, d30, d31
}
schedHour.3.98.111.98.6.105.102.45.111.102.102 = { h20 }
schedMinute.3.98.111.98.6.105.102.45.111.102.102 = { m30 }
schedValue.3.98.111.98.6.105.102.45.111.102.102 = down(2)
schedContextName.3.98.111.98.6.105.102.45.111.102.102 = ""
schedVariable.3.98.111.98.6.105.102.45.111.102.102 =
    ifAdminStatus.6

```

```

schedType.3.98.111.98.6.105.102.45.111.102.102 = calendar(2)
schedAdminStatus.3.98.111.98.6.105.102.45.111.102.102 = enabled(1)
schedStorageType.3.98.111.98.6.105.102.45.111.102.102 =
    nonVolatile(3)
schedRowStatus.3.98.111.98.6.105.102.45.111.102.102 = active(1)

```

The scheduling entry which brings the interface up on every Monday morning at 5:30 is owned by schedOwner = "bob" and its name is schedName = "if-on". The instance identifier for the scheduling entry is therefore 3.98.111.98.5.105.102.45.111.110.

The entry in the schedTable which brings the interface up again on every Monday morning at 5:30 looks as follows:

```

schedWeekDay.3.98.111.98.5.105.102.45.111.110 = { monday }
schedMonth.3.98.111.98.5.105.102.45.111.110 = {
    january, february, march, april, may, june,
    july, august, september, october, november, december
}
schedDay.3.98.111.98.5.105.102.45.111.110 = {
    d1, d2, d3, d4, d5, d6, d7, d8, d9, d10,
    d11, d12, d13, d14, d15, d16, d17, d18, d19, d20,
    d21, d22, d23, d24, d25, d26, d27, d28, d29, d30, d31
}
schedHour.3.98.111.98.5.105.102.45.111.110 = { h5 }
schedMinute.3.98.111.98.5.105.102.45.111.110 = { m30 }

schedValue.3.98.111.98.5.105.102.45.111.110 = up(1)
schedContextName.3.98.111.98.5.105.102.45.111.110 = ""
schedVariable.3.98.111.98.5.105.102.45.111.110 = ifAdminStatus.6

schedType.3.98.111.98.5.105.102.45.111.110 = calendar(2)
schedAdminStatus.3.98.111.98.5.105.102.45.111.110 = enabled(1)
schedStorageType.3.98.111.98.5.105.102.45.111.110 = nonVolatile(3)
schedRowStatus.3.98.111.98.5.105.102.45.111.110 = active(1)

```

A similar configuration could be used to control other schedules. For example, one could change the "if-on" and "if-off" schedules to enable and disable the periodic scheduler defined in the first example.

## 6. Security Considerations

There are a number of management objects defined in this MIB that have a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations.

SNMPv1 by itself is not a secure environment. Even if the network itself is secure (for example by using IPSec), even then, there is no control as to who on this secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB.

It is recommended that the implementers consider the security features as provided by the SNMPv3 framework. Specifically, the use of the User-based Security Model RFC 2574 [RFC2574] and the View-based Access Control Model RFC 2575 [RFC2575] is recommended.

It is then a customer/user responsibility to ensure that the SNMP entity giving access to an instance of this MIB, is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

Scheduled SNMP set operations must use the security credentials that were present when the corresponding row in the scheduling entry was created. An implementation must therefore record and maintain the credentials for every scheduling entry.

An implementation must ensure that access control rules are applied when doing the set operation. This is accomplished by calling the `isAccessAllowed` abstract service interface defined in RFC 2571 [RFC2571]:

```
statusInformation =          -- success or errorIndication
  isAccessAllowed(
    IN  securityModel          -- Security Model in use
    IN  securityName          -- principal who wants to access
    IN  securityLevel          -- Level of Security
    IN  viewType              -- read, write, or notify view
    IN  contextName           -- context containing variableName
    IN  variableName          -- OID for the managed object
  )
```

The `securityModel`, `securityName` and `securityLevel` parameters are set to the values that were recorded when the scheduling entry was created. The `viewType` parameter must select the write view and the `contextName` and `variableName` parameters are taken from the `schedContextName` and `schedVariableName` values of the scheduling entry.

This MIB limits scheduled actions to objects in the local MIB. This avoids security problems with the delegation of access rights. However, it might be possible for a user of this MIB to own some schedules that might trigger far in the future. This can cause security risks if the security administrator did not properly update the access control lists when a user is withdrawn from an SNMP engine. Therefore, entries in the `schedTable` SHOULD be cleaned up whenever a user is removed from an SNMP engine.

To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model (VACM) defined in RFC 2575 [RFC2575] for tables in which multiple users may need to independently create or modify entries, the initial index is used as an "owner index". Such an initial index has a syntax of

SnmpAdminString, and can thus be trivially mapped to a securityName or groupName as defined in VACM, in accordance with a security policy.

All entries in related tables belonging to a particular user will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the "column" subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask "wildcarding" the column subidentifier. More elaborate configurations are possible.

## 7. Intellectual Property

The IETF takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on the IETF's procedures with respect to rights in standards-track and standards-related documentation can be found in BCP 11, RFC 2028. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementors or users of this specification can be obtained from the IETF Secretariat.

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to practice this standard. Please address the information to the IETF Executive Director.

## 8. Changes from RFC 2591

The following list documents major changes from the previous version of this document, published as RFC 2591:

- Updated the SNMP Management Framework boilerplate and the references.
- Added revision clauses to the module identity macro.
- Clarified the behavior during time transitions.

- Clarified that schedInterval and schedCalendarGroup objects can be modified regardless of the current value of schedRowStatus, schedAdminStatus and schedOperStatus.
- Added some additional boilerplate text to the security considerations section.
- Clarified that implementations must re-calculate any pending action invocations when scheduling parameters are modified.
- Clarified that schedOperStatus must not be enabled while the schedRowStatus is not active.
- Clarified that schedRowStatus can not be changed as long as the schedOperStatus is enabled.
- Clarified that implementations can delegate the isAccessAllowed check by sending themselves an SNMP Set message.
- Added the schedTriggers object which counts the total number of triggers.
- Added DEFVALs for schedContextName, schedVariable, and schedValue and updated the schedRowStatus description.
- Deprecated schedCompliance, schedGroup and created schedCompliance2 and schedGroup2 that take care of the new schedTriggers object.

## 9. Acknowledgments

This document was produced by the IETF Distributed Management (DISMAN) working group.
